1. Computational Details

1.1 Transition State Search

All density functional theory (DFT) calculations were performed using the Gaussian 16 suite of programs (revision A3).¹ The B3LYP functional was used to investigate the reaction pathways.² Geometry optimizations for the ground states, transition states and products were performed with the LANL2DZ pseudopotential for palladium (Pd)³ and the 6-31G(d)⁴ basis set for all other atoms. The stationary points are characterized via calculations of the analytical gradients and Hessians. Intermediates and transition states were identified by the observation of the correct number of imaginary eigenvalues in the Hessian matrix: zero (0) and one (1) respectively. To refine the results, single point energy calculations were performed on the gas-phase optimized structures. This was performed using four different methods (1) M06 functional⁵ with the LANL2DZ pseudopotential for Pd and the 6-311+g(d,p) basis set⁶ for all other atoms (2) B3LYP functional² with Grimme's GD3-BJ dispersion correction⁷ with the def2-TZVP pseudopotential for Pd⁸ and the 6-311++G(d,p) basis set for all other atoms (3) M06-2X functional⁵ with Grimme's GD3 dispersion correction⁹ with the def2-TZVP pseudopotential for Pd and the 6-311++G(d,p) basis set for all other atoms and (4) wB97x-D functional¹⁰ the def2-TZVP pseudopotential for Pd and the 6-311++G(d,p) basis set for all other atoms. All quoted free energies are reported at 298.15 K in THF and were calculated via the SMD¹¹ continuum solvation model. To evaluate the effect of electronic properties on selectivity, a full Natural Bond Orbital (NBO) analysis was performed in Gaussian using version 3.1 of the NBO program at the B3LYP/6-31G(d,p) level of theory.¹²

These calculations were performed for 30 ligands; 17 training, 10 validation I, and 3 validation II ligands. Structures of the ligands used in this study are depicted in Table S1.

Table S1. Structures used in this study. L1-L17 were used as the training set, L18-L27 served as validation set I, and L28-L31 served as validation set II.

1.2 Dispersion Calculations

To study the origin of the dispersion interactions between the ligands and the substrate, separate dispersion calculations were performed for groups that were informed to experience such interactions via visual inspection. Grimme's GD3 was used to evaluate empirical dispersion. Dispersion interactions were evaluated between the substrates, the lower aryl ring and the substrates, and the *t*-butyl group and the substrates. The geometries for each of these dispersion calculations were taken from the optimized transition state structures. To isolate the structures of interest to evaluate dispersion, per Peng Liu's method¹³, C-C and C-Pd bonds were cleaved and atoms that were not of interest were deleted. Hydrogen atoms were added to dangling carbon atoms at a distance of 1.07 Å in the same direction as the cleaved bonds (Figure S1).¹³

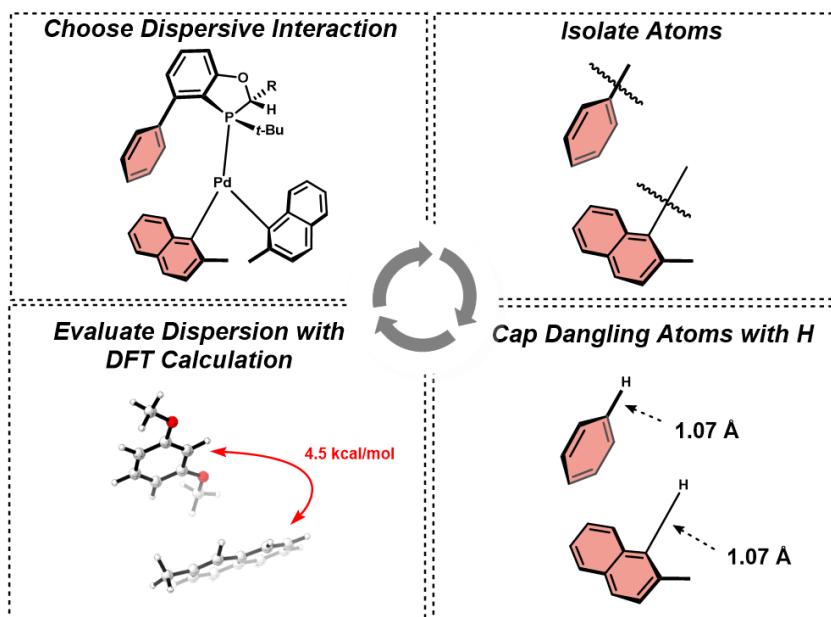

Figure S1. General procedure for calculating dispersion interactions. Isolation of atoms of interested were followed by hydrogen capping and DFT calculations using Grimme's GD3 dispersion correction.

Calculations of the dispersive interaction energies were based on density functional theory (DFT) calculations using the Gaussian 16 suite of programs (revision A3). Single point energy calculations were performed using the M06 functional and the 6-311+G(d,p) basis set with Grimme's GD3 dispersion correction¹⁰. Figure S2 details the dispersive interactions evaluated for the model.

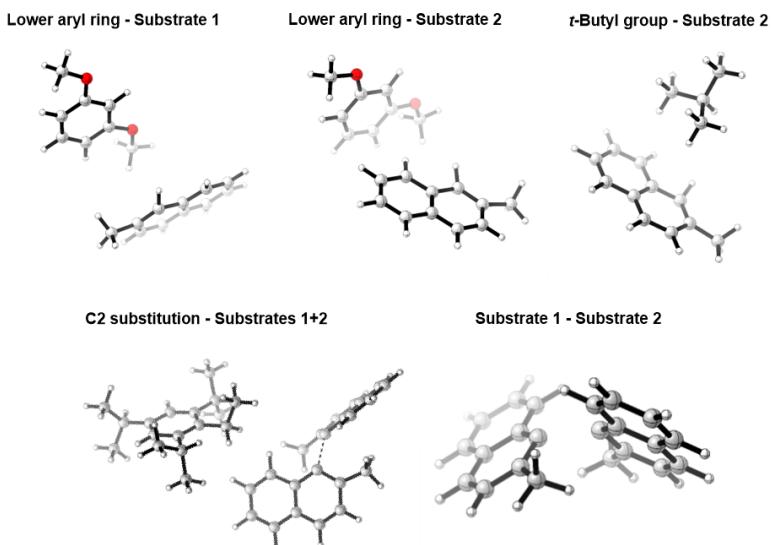

Figure S2. Dispersive interactions analyzed in this study. Molecular representations were generated with CYLview20.

1.3 Feature Extraction

Before features could be extracted for the model, atoms from the DFT calculations were labeled manually. Due to the small size of the dataset and the consistent backbone structure of the ligand, a standard numbering scheme was used for each ligand as depicted in Scheme S1. A python script was used to extract molecular, atomic, and electronic features from Gaussian output files, and all features are listed in Table S2 (source code is available at: <https://github.com/Newhouse-Group/6-Endo-Radical-Cyclization>).

Scheme S1. Numbering scheme used to extract atomistic and molecular features.

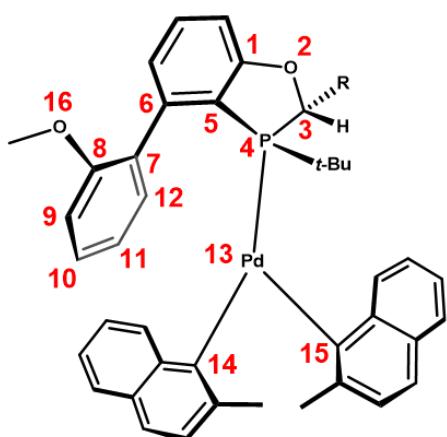

Table S2. Categories of atomic, molecular, and electronic features extracted to use as input for the model.

Dipole Moment	Dihedral Angles	Core Electron Population	NMR Shifts
Bond Lengths	Total Charge	Valence Electron Population	γ -ness
Bond Angles	Charge	Rydberg Population	Puckered Deviation 360°
Imaginary Frequency	ΔG	HOMO/LUMO	Dispersion
Electronegativity	Hardness	Electrophilicity	Sterimol

2. Machine Learning Models

Dimension reduction and machine learning models were created in Google Collaboratory using Python version 3.8. Neural networks (NNs) were generated with PyTorch version 1.13.1+c116. All NNs were generated via the leave-one-out (LOO) cross-validation method due to the small size of the dataset.

2.1 Feature Reduction

Because the training set comprised of only 17 ligands and there were >150 features extracted from the DFT calculations, feature reduction techniques needed to be used to avoid overfitting. Principal Component Analysis (PCA)¹⁴ was first attempted to reduce the ~150 features to 15 (Figure S3A). Additionally, Sammon Mapping¹⁵, was utilized (Figure S3B). Whereas PCA aims to highlight the most descriptive components of a given dataset, Sammon Mapping maps higher dimensional data to lower dimensional data by preserving the inner point distances of the original data. Both models showed moderate performance, however we still sought to find another technique to improve the predictions.

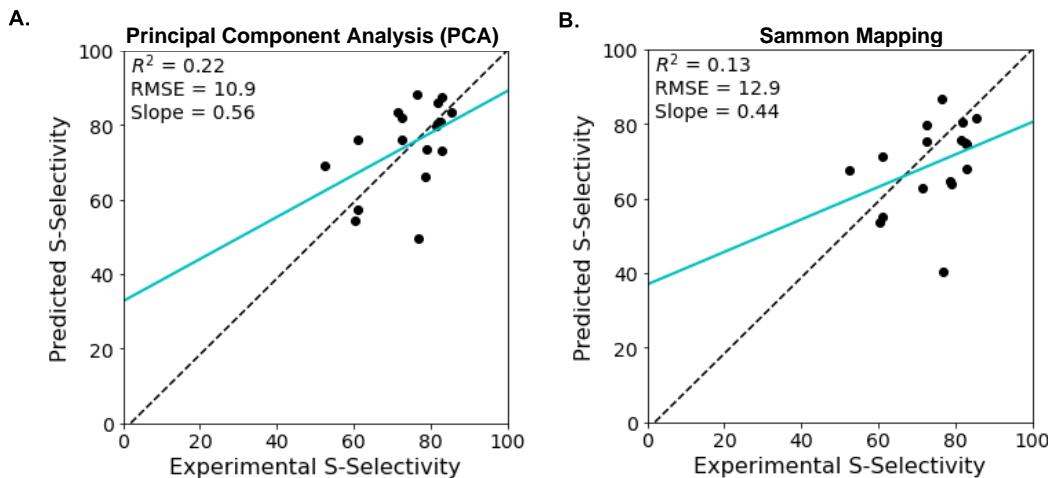

Figure S3. (A) NN performance after reducing ~150 features down to 15 using PCA. (B) NN performance after reducing ~150 features down to 15 using Sammon Mapping.

The third method we attempted to use was correlating the features to the selectivity of the reaction. The fifteen features with the highest R^2 value were then selected as the input features for the model. Electronic features, especially about the C2 position on the oxaphosphole ring, appeared to be dominating factors for determining selectivity. Geometric features, including bond lengths and angles involving the C2 and P were also important features for determining selectivity. Additionally, geometries about the transition state were also important and are highlighted in Figure S4. Creating a NN with this method of feature selection showed to be the most effective method. The model was created according to the procedure outlined above.

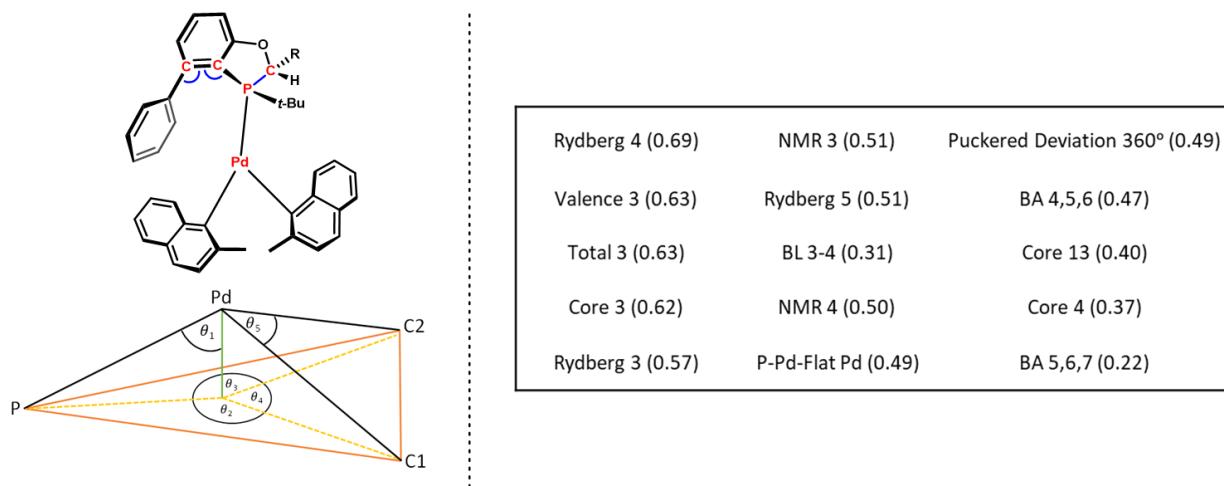

Figure S4. (left) Highlighted in red are atoms with features that experienced the highest correlation to selectivity. Highlighted in blue are bond lengths/angles that were also highly correlated. The bottom diagram depicts interesting geometries about the transition state involving Pd. (right) Top 15 features used as inputs for the NN model. In parenthesis are the R^2 value to selectivity.

2.2. Neural Network Architectures

With the method of feature selection finalized, the hyperparameters of the NN were adjusted to evaluate for optimal performance. The first round of optimizations involved changing the activation function in the hidden layers (Table S3). The Rectified Linear Unit (ReLU) had the best overall performance, while the leaky ReLU and softplus performed only marginally worse. Because the feature for the models were chosen based on how high their R^2 value was to the enantioselectivity, the model built with only linear layers also performed relatively well compared to the other activation functions.

In addition to the activation functions, the number of hidden layers and the number of nodes in those hidden layers were also varied (Table S3).

Table S3. Comparative performance of different NN architectures. The best overall performance used the ReLu activation function, 2 hidden layers and 15 nodes in each layer.

Category	Change	R2	RMSE	Slope
Activation Function	Sigmoid	0.02	29.25	-0.01
	Hyperbolic Tangent	0.01	28.58	-0.01
	Linear	0.43	7.84	0.65
	Softplus	0.52	6.94	0.67
	Leaky ReLu	0.52	6.89	0.67
	ReLu	0.52	6.85	0.69
Number of Hidden Layers	1	0.52	7.02	0.70
	3	0.52	6.85	0.69
	4	0.52	6.85	0.69
	2	0.52	6.85	0.69
Number of Nodes	5	0.29	8.09	0.36
	25	0.52	6.89	0.66
	15	0.52	6.85	0.69

A graphical representation of the model's performance as well as a comparison of reported and predicted selectivities are outlined in Figure S5 and Table S4 respectively.

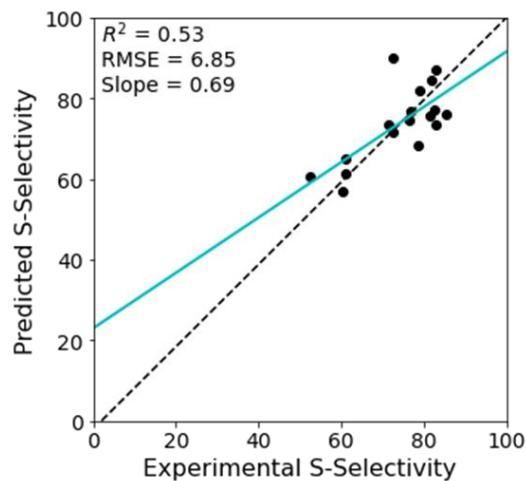

Figure S5. Final model performance on the training data set. Plotted points are LOO predictions.

Table S4. Comparison of reported and predicted values for selectivity of the training set with the final NN architecture.

Ligand	Experimental	Predicted	Ligand	Experimental	Predicted	Ligand	Experimental	Predicted
L1	52.5	60.7	L7	83.0	73.7	L13	77.0	77.0
L2	78.5	68.3	L8	85.5	75.9	L14	60.5	57.1
L3	81.5	76.0	L9	71.3	73.6	L15	61.0	61.3
L4	82.5	77.1	L10	85.0	71.7	L16	61.0	65.2
L5	72.5	90.2	L11	82.0	84.5	L17	79.0	81.8
L6	76.5	74.6	L12	83.0	87.0			

This final architecture was compared to a version in which $\Delta\Delta G^\ddagger$ was used as an input feature in the NN using the single-point energy calculations at the wb97x-D/6-311++G(d,p)-def2-TZVP(Pd) level of theory. Table S5 shows a direct comparison between the two models.

Table S5. Comparison of the final NN architecture with the top 15 features compared to including the $\Delta\Delta G^\ddagger$ as an input feature.

Model	R2	RMSE	Slope
Top 15 Features	0.52	6.85	0.69
Top 14 Features + $\Delta\Delta G^\ddagger$	0.47	7.47	0.65

2.3 Tests for Overfitting

Although we took preventative steps to avoid overfitting, it is still necessary to perform the necessary checks to ensure that this is not the case. Various randomization tests were performed to evaluate for overfitting. If this model performs well with this random data, then that indicates that the model was not finding chemically meaningful information amongst the training data and cannot extrapolate to unseen validation data.

The randomization tests used for this study were (1) X-randomization, (2) Y-shuffling, and (3) Y-randomization. X-randomization involves assigning random values to be used as input features to the model (Figure S6A). For Y-shuffling, the enantioselectivity labels of the training data are randomly assigned to each of the training points (Figure S6B). Y-randomization involves assigning random labels (values of enantioselectivity) to the training data (Figure S6C). The low levels of correlation observed by using any of these methods (0.17, 0.00, and 0.00) as well as the slopes being significantly closer to 0 than to 1 (0.01, 0.00, and 0.03) indicates that this NN is not describing the random error of the training data rather than relationships between the variables. Confident that the model was not overfit with these tests, we could continue forward with predicting the enantioselectivity of ligands that were not included in the training set.

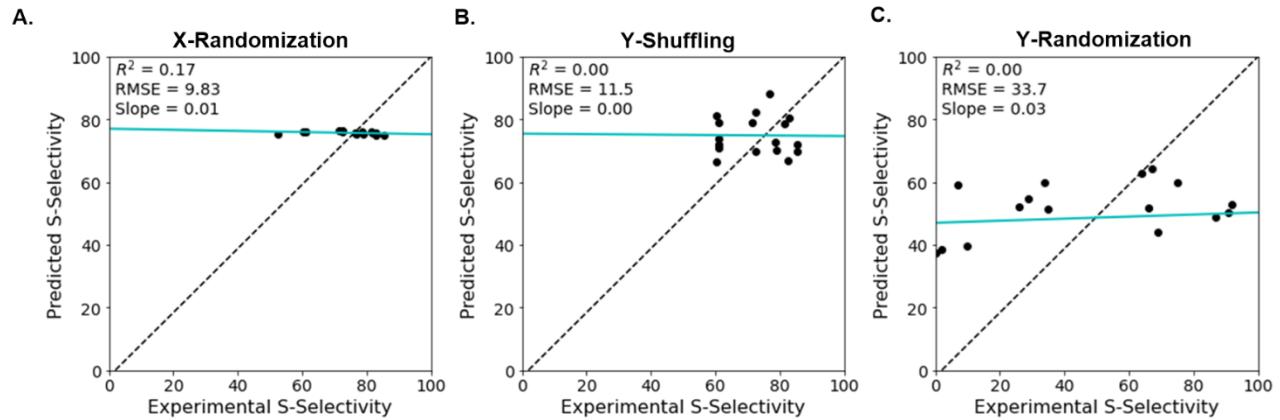

Figure S6. (A) Model created with random x-data as the input features. (B) Model created by randomly assigning each training point with a selectivity label. (C) Model created by randomly generating selectivity labels for each of the training points.

2.5 Validation Set Predictions

When creating these models, there were multiple options for selectivity labels to use for the training. These include; enantiomeric excess (ee), enantiomeric ratio (er), the natural logarithm of the er ($\ln(er)$), S-selectivity, and *R*-selectivity. Figure S7 shows the training performance for each of these measures of selectivity using the LOO method for L1-L17.

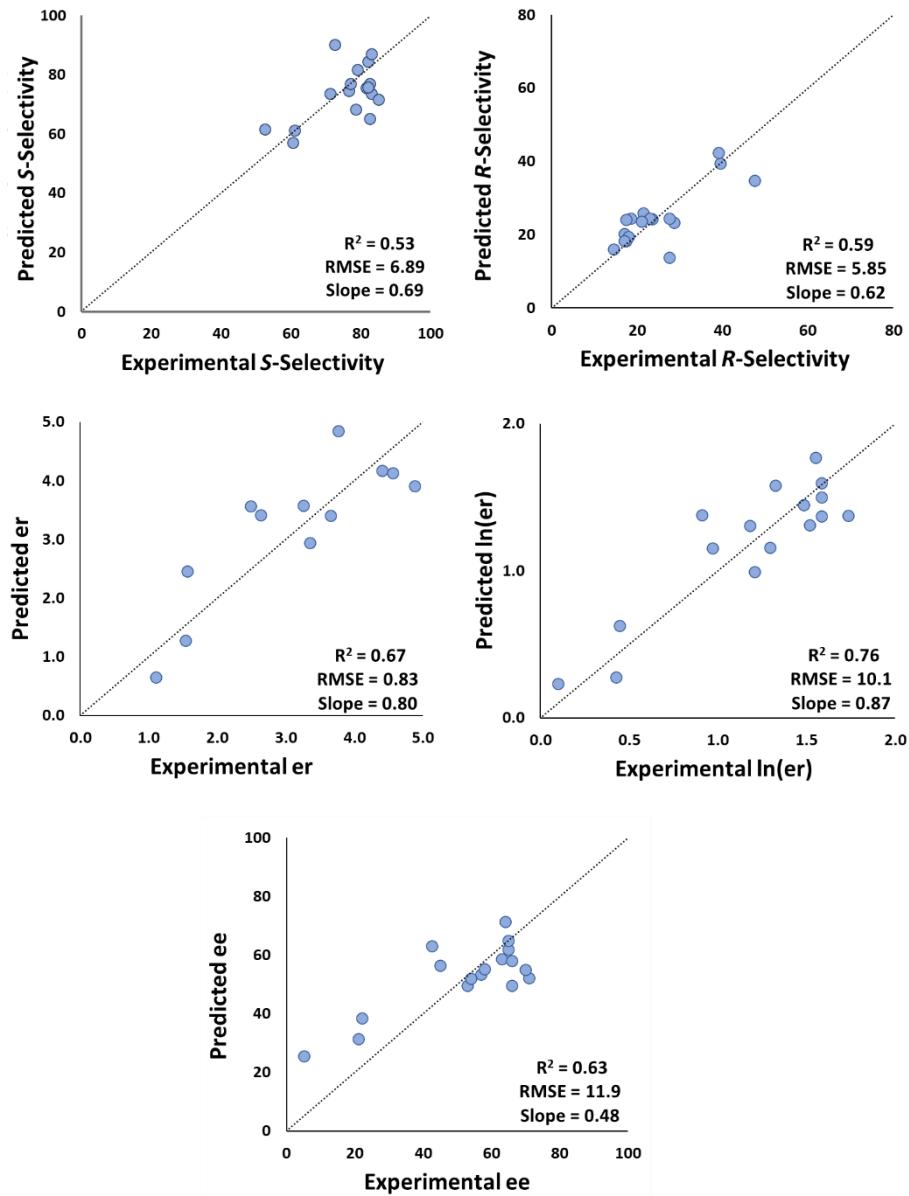

Figure S7. Models built using *S*-selectivity, *R*-selectivity, ee, er, and ln(er) as labels. Model performance was evaluated with the R^2 , RMSE, and slope shown in the bottom right corner of each of the plots.

It was evident from these plots that any of these measures of selectivity could provide promising predictions for the validation set. To test these models, 10 of the 13 validation points (L18-L27) were evaluated on each of the models to determine which would be the best model to move forward with. Ligands for the validation sets were strictly chosen based on availability. Figure S8 shows the performance of each of these five models with the first validation set.

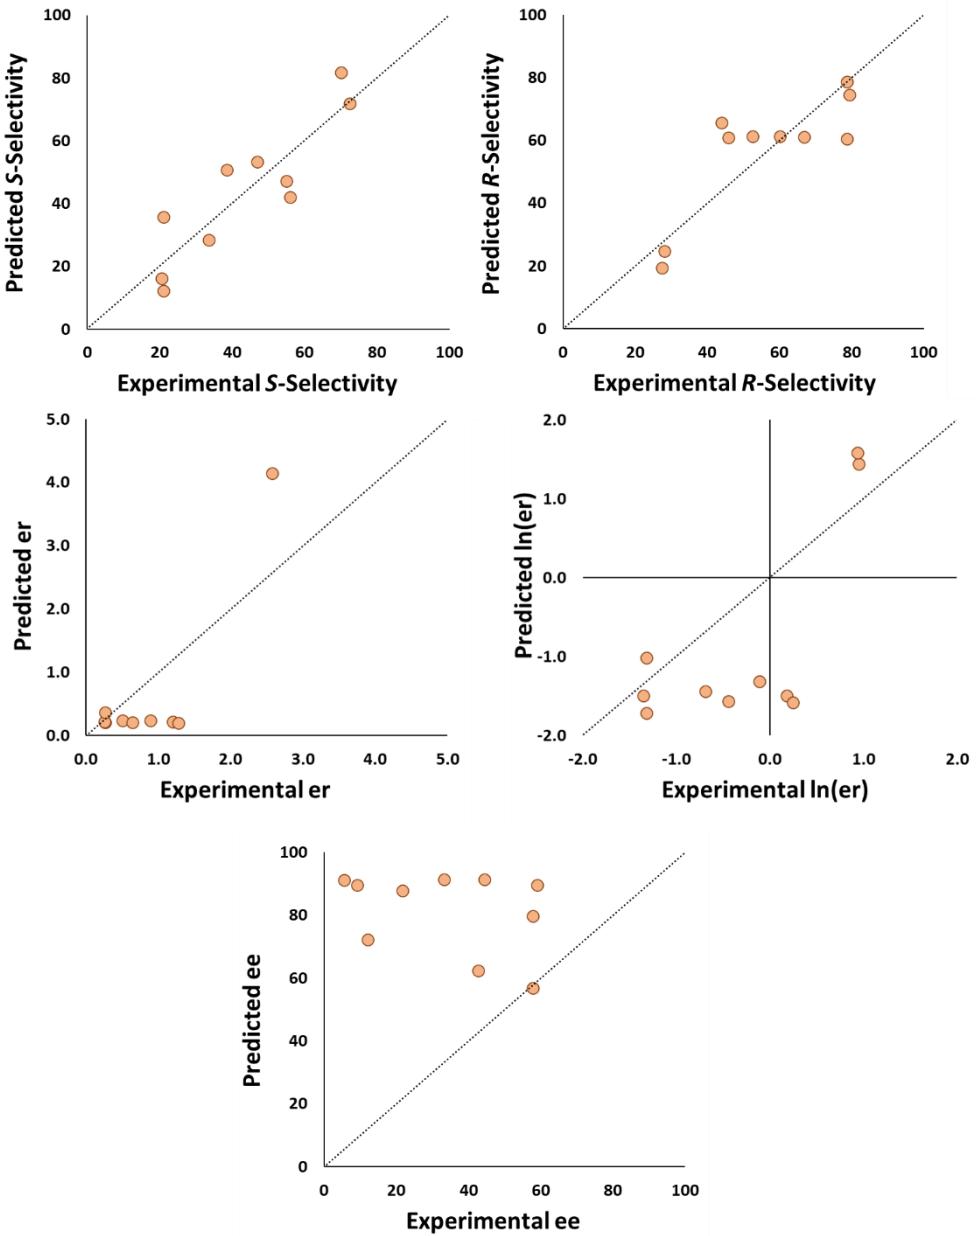

Figure S8. Models built using *S*-selectivity, *R*-selectivity, ee, er, and ln(er) as labels. Performance of the trained models with a validation set of ten ligands (L18-L27).

Evident from these plots, the model trained with *S*-selectivity as the label outperformed the other models. The other four models appear to regress to the mean rather than make meaningful predictions from the chemical data.

Because the validation data was essentially fit to five different models when choosing the final one, an additional validation set of three ligands (L28-L30) was tested with the *S*-selectivity model. Results of validation set I (orange points) and validation set II (green points) for *S*-selectivity are shown in Figure S9.

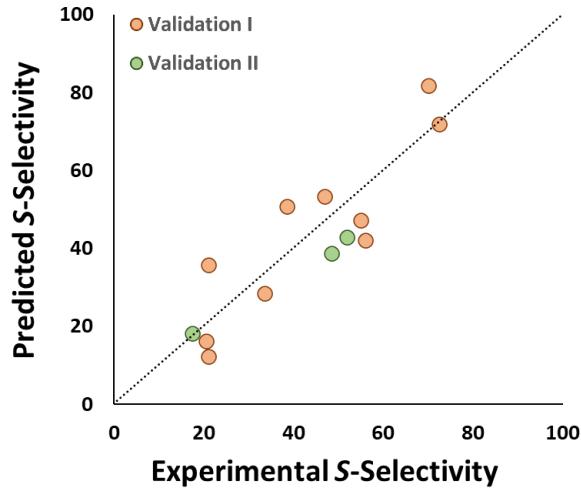

Figure S9. Performance of the final model on validation set I and II.

Figure S10 details the predictions for each of the ligands.

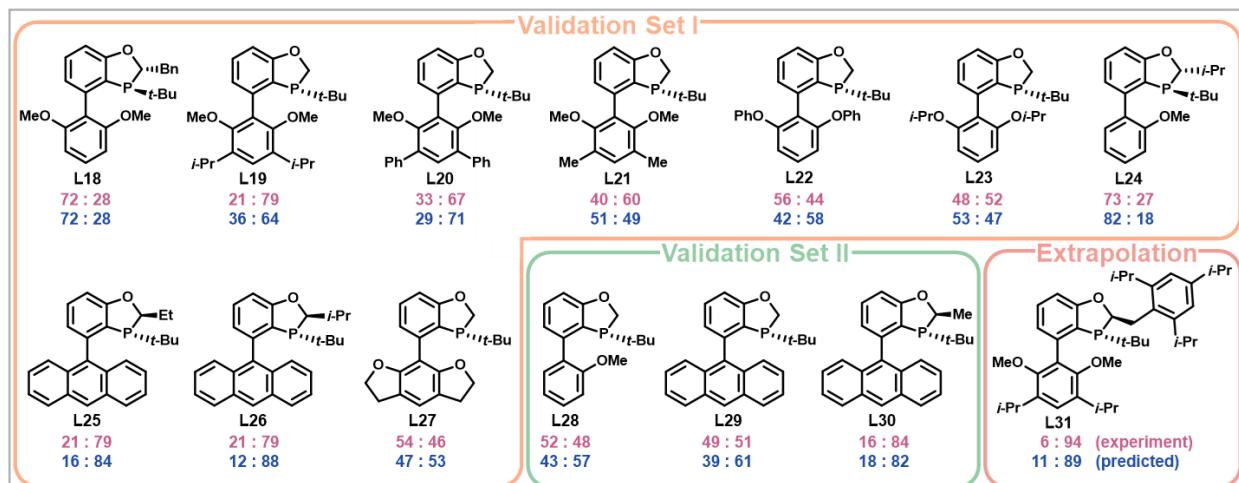

Figure S10. Comparison of experimental and predicted values for S-selectivity of validation set I and II.

A series of extrapolation ligands were designed by manual inspection of the training and test sets. Five structures were designed based on trends that, seemingly, positively influenced ligands to be more selective. The design of and subsequent DFT calculation and prediction generation of these proposed structures was complete in about a day's time. The structure of these five proposed structures and their predicted selectivity is shown in Figure S11. L31 was ultimately chosen as the sole ligand for experimental extrapolation due to it yielding the best predicted selectivity.

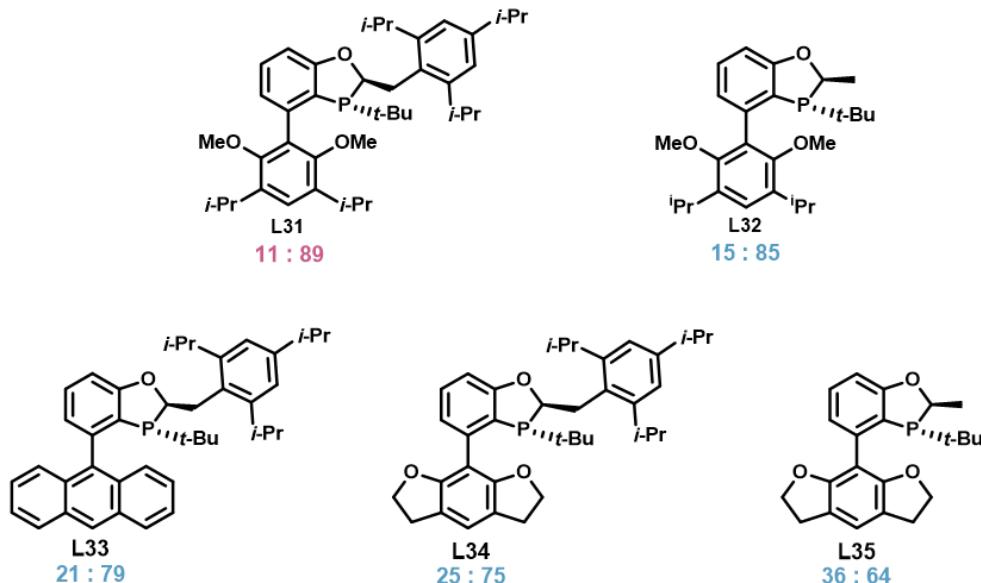

Figure S11. Proposed extrapolation ligands and their predicted selectivity.

2.4 Other Approaches to Modeling

2.4.1 Ligand-Only Model

For this particular model of the Negishi reaction, the structure of the substrate and the conditions of the reaction remained constant. To simplify the model from requiring transition state calculations, we created a model based on features from calculations of only the ligand. Calculations were performed for these structures in the same manner as outlined in section 1.1.

The same features were used for this model as the transition state model. The transition states had additional features that were not present in the calculations of only the ligand (puckered deviation from 360° and P-Pd-Flat Pd). To replace these two features in the ligand-only model, features of the ligand-only model were again correlated to selectivity. The two highest correlated features were then used in their place (Core 5 and Rydberg 2). The performance of the training set (pink points) and validation set (green points) are shown in in Figure S12.

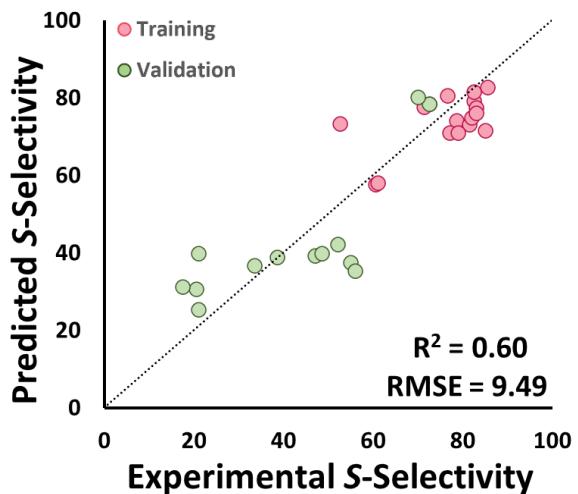

Figure S12. Performance of ligand-only model on training set, validation set I and II. Depicted R^2 and RMSE are in reference to the validation sets.

2.4.2 GFN2-xTB Model

To resemble the transition state DFT calculations as much as possible, the highest energy point along the C-C reaction coordinate was determined with GFN2-xTB¹⁶, from here on called pseudo transition state (pseudo-TS). Pseudo-TSs were located via traversing across the reaction coordinate of the potential energy surface by gradually decreasing the distance between C14 and C15 from 3.0 to 1.0 Å in 200 evenly spaced increments. When the energy reached a maximum, the structure was isolated. To obtain the same features as the DFT TS calculations, subsequent single-point energy and NBO calculations were performed on these optimized structures using Gaussian. Unlike the ligand-only model, all features present in the DFT TS calculations were also present in the GFN2-xTB pseudo-TSs. Therefore, the same features used to construct the DFT TS model were used to create the GFN2-xTB pseudo-TS model. Performance of this model is shown in Figure S13.

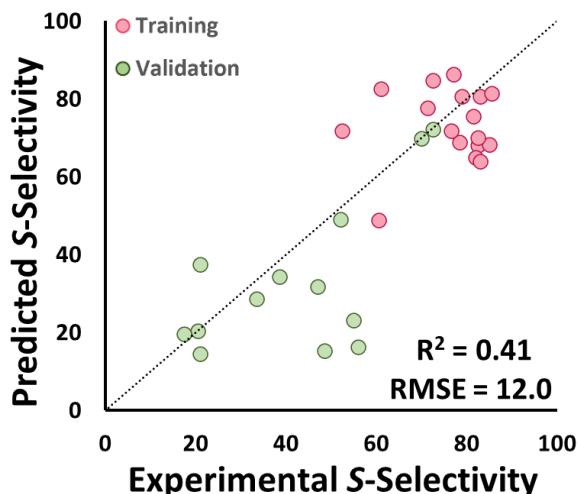

Figure S13. Performance of GFN2-xTB pseudo-TS model on training set, validation set I and II. Depicted R^2 and RMSE are in reference to the validation sets.

Table S6 shows the prediction capabilities of the DFT TS and GFN2-xTB pseudo-TS models with the validation set. L29, L30, L25, and L26 differ only by C2 substitution on the oxaphosphole ring. With only hydrogens at the C2 position on L29, the DFT TS captured the poor selectivity exhibited by this ligand as compared to the others. GFN2-xTB struggled to capture the poor selectivity and instead predicted that it would have similar selectivity to the other ligands.

Table S6. Comparison of the performance of DFT TS and GFN-2xTB pseudo-TS models on select validation set ligands. All values are reported in terms of % *S*-selectivity.

Ligand	Experiment	DFT TS	GFN-2xTB Pseudo-TS
L29 	48.6	38.7	15.3
L30 	16.5	18.4	19.7
L25 	20.5	16.2	20.4
L26 	21.2	12.2	14.5

2.4.3 $\Delta\Delta G^\ddagger$

A model using the difference in energy between the Pro-*S* and Pro-*R* transition states was also created. Using the geometry optimizations and single-point energy calculations, $\Delta\Delta G^\ddagger$ was calculated by subtracting the energy of the Pro-*R* transition state from the Pro-*S* energy. Using Gibb's free energy equation, a linear regression was fit to the data. Using this regression, the $\Delta\Delta G^\ddagger$ of validation set I and II was then used to predict the selectivity of these ligands. The resulting performance of this method is shown in Figure S14. Three different methods for single point calculations were tried. All calculations were performed with the 6-311++G(d,p) basis set for light atoms and the def2-TZVP basis set for Pd. The functional used is indicated above the plot in Figure S14.

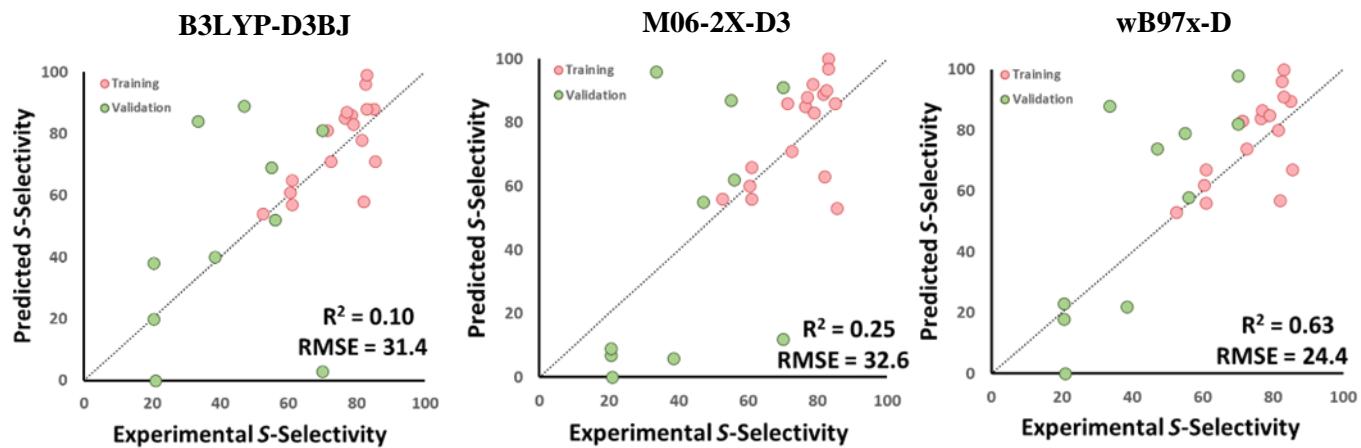

Figure S14. Performance of DFT $\Delta\Delta G^\ddagger$ model on training set, validation set I and II. Depicted R^2 and RMSE are in reference to the validation sets. Three plots refer to different functionals used in the single-point energy calculations.

2.4.4 Other ML Models

Alternative methods to a NN were explored. These methods include random forest (RF), logistic regression, k-Nearest Neighbors (kNN), support vector regression (SVR), decision tree (DT), gradient boosting (GB), and bagging. All methods were implemented in Python using scikit-learn version 1.2.2. Table S7 highlights the performance of these different methods by comparing their R^2 values, RMSE, and slopes.

Table S7. Performance of 6 different ML models for predicting enantioselectivity of the asymmetric Negishi reaction. Shown are model R^2 values, RMSE, and slopes.

	RF	Logistic Regression	kNN	SVR	DT	GB	Bagging
R2	0.51	0.22	0.26	0.52	0.14	0.52	0.39
RMSE	6.63	9.39	8.52	10.5	11.9	6.65	7.35
Slope	0.46	0.38	0.17	0.00	0.44	0.60	0.41

Multivariate linear regression (MLR) was also attempted using the five features that were the most correlated to selectivity (Core 3, Rydberg 4, Bond Length 3-4, Valence 3, Total 3). Figure S15 shows the performance of the MLR model as well as statistics regarding the R^2 and RMSE.

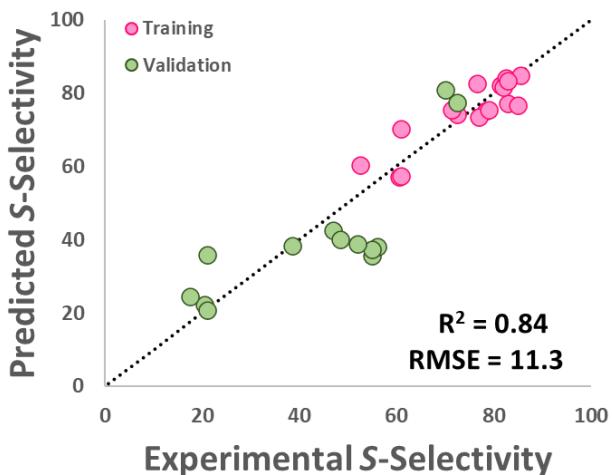

Figure S15. Performance of MLR model on training set, validation set I and II. Depicted R^2 and RMSE are in reference to the validation sets.

2.5 Feature Space

Figure S16 shows two examples of the chemical space of four different features.

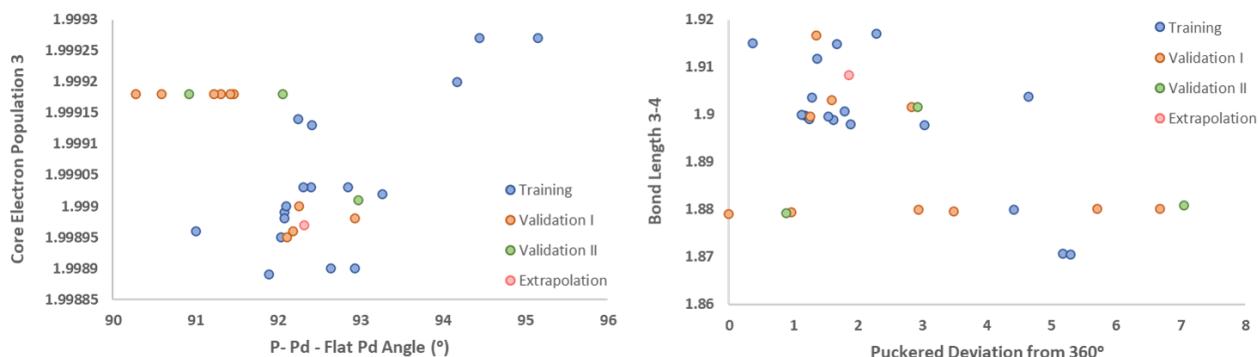

Figure S16. (Left) Chemical space analysis of the core electron population of atom 3 and P-Pd-Flat Pd bond angle. (Right) Chemical space analysis of the bond length between atom 3 and 4 and the puckered deviation from 360° .

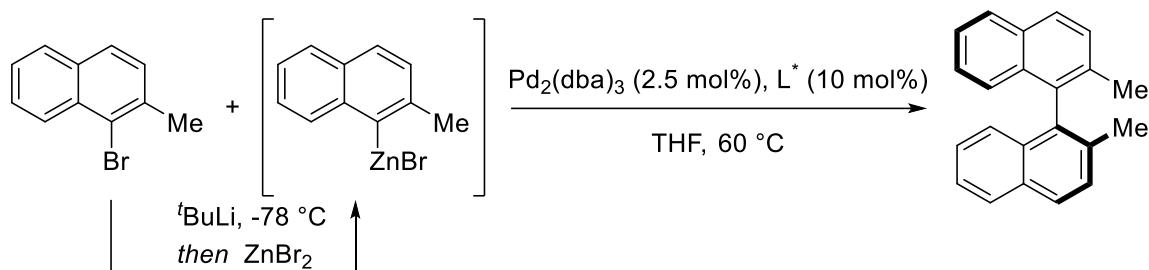

These plots show that some of the validation I and II data points (orange and green points, respectively) fall within the chemical space, or cluster, of training points (blue points). Also evident from these plots is that some of the validation set points lie outside the chemical space of the training points. This indicates that this model can extrapolate to predict the selectivity of ligands whose features do not necessarily resemble those of the training set.

3.0 Experimental Details

3.1 General Procedure

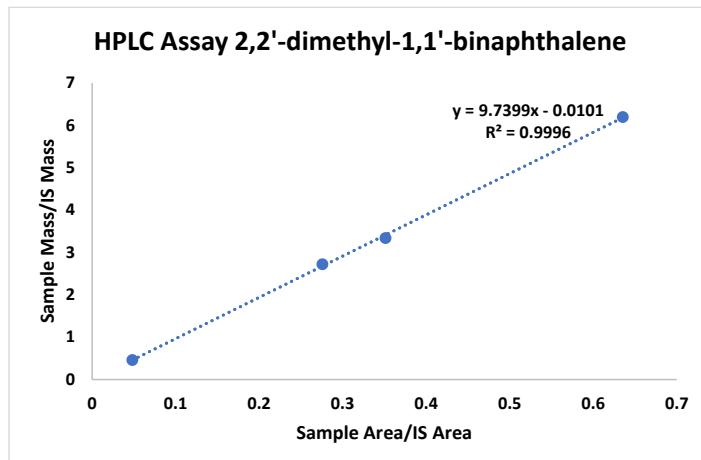

All reactions were conducted in oven-dried glassware under an inert atmosphere of nitrogen or argon with magnetic stirring unless otherwise noted. THF (<0.02% water content) and MeOH were purchased from Sigma Aldrich and used directly without further purifications. 1.6 M *Tert*-butyllithium and zinc bromide were purchased Sigma Aldrich and were used directly. Pd₂(dba)₃ was purchased from Strem Chemicals and was used directly. Ligands L18, L19¹⁷, L20¹⁷, L21¹⁷, L22¹⁷, L23¹⁷, L24¹⁷, L25¹⁸, L26¹⁷, L27¹⁷, L28¹⁷, L29¹⁷, L30¹⁷, and L31 were purchased from Zejun Pharmaceuticals and were directly used. (*S*)-2,2'-dimethyl-1,1'-binaphthalene was synthesized using a literature procedure.¹⁹

General procedure for the asymmetric Negishi cross-coupling.

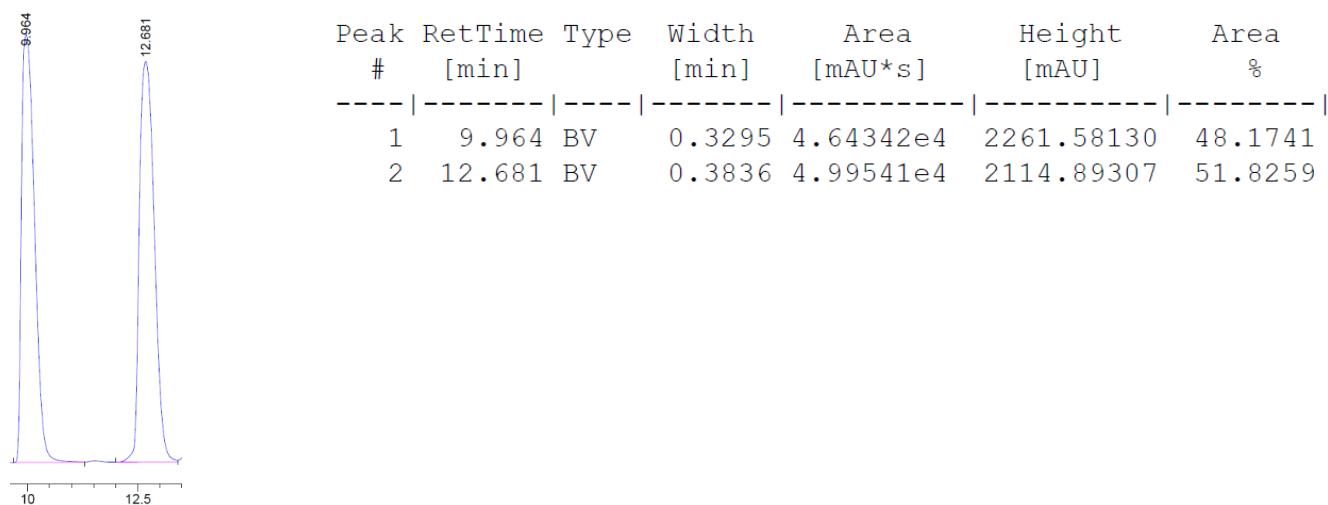

To a 20 mL vial equipped with a magnetic stir bar, 1-bromo-2-methylnaphthalene (0.059 g, 0.267 mmol, 1 equiv.) was then added under nitrogen followed by tetrahydrofuran (1 mL, 0.3 M). The reaction was then cooled to -78 °C where a solution of *tert*-butyllithium in pentanes (1.6 M, 0.5 mL, 0.801 mmol 3.0 equiv.) was added dropwise while keeping the reaction at -78 °C. After 20 min, a solution of zinc bromide (0.12 gm, 0.534 mmol, 2.0 equiv.) in tetrahydrofuran (1 mL) was added dropwise to the reaction while keeping the reaction at -78 °C. After 5 minutes, the reaction was allowed to warm to room temperature and stirred for further 15 minutes. During this time, to a second Agilent 20 mL vial equipped with a magnetic stir bar, 1-bromo-2-methylnaphthalene (0.088 gm, 0.4 mmol, 1.5 equiv.), Pd₂(dba)₃ (0.006 gm, 0.007 mmol, 2.5 mol%), and ligand (10 mol%) were added in the glovebox followed by tetrahydrofuran (0.25 mL) under nitrogen. The reaction mixture was stirred at room temperature for 2-3 minutes. The organozinc solution was then cannulated into the second vial. The combined mixture was then placed in a pre-heated 60 °C oil bath and allowed to stir for 16 h. After cooling the reaction to room temperature, the reaction mixture was quenched with methanol (1 mL). 4,4'-di-*tert*butylbiphenyl (HPLC internal standard) followed tetrahydrofuran (1 mL) were added. Yields were obtained by HPLC. Calibration curve for 2,2'-dimethyl-1,1'-binaphthalene was obtained by adding a variable amount of 2,2'-dimethyl-1,1'-binaphthalene (9.8 mg, 53.3 mg, 73.8 mg, 124 mg) and 4'4'-di-*tert*-butylbiphenyl as an internal standard (20.5 mg, 19.3 mg, 23.3 mg, 20.0 mg) in tetrahydrofuran.

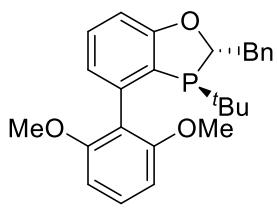

3.2 Characterization Data for the Validation Set

Enantiomeric excess was determined by chiral HPLC on a ChiralPAK OD-3 (3 μ m, 4.6 x 250 mm, 100% hexanes, isocratic, 0.8 mL/min, run time: 25 min, 25 °C, Sig 220, 10 Ref = 500, 100, 9.96 min (S), 12.68 min (R)).
